

I hosted my application using GitHub Pages by creating a repository and uploading my HTML file. I converted my original Python program into a web-based version using HTML and JavaScript so it could run in a browser. One challenge I faced was that Python input functions do not work on static websites, so I solved this by using input fields and JavaScript logic instead. After enabling GitHub Pages in the repository settings, my app became accessible online through a live link. Cloud hosting makes projects more useful because anyone can access them without installing software. It also allows easy sharing and improvement of applications. This experience helped me understand how code can be deployed beyond my local computer.
